FOCUS AREA: COASTAL CLIMATE

what is coastal climate?
Climate is the long-term average weather conditions (seasonal-to-millennial periods) that are characteristic of a region like the Carolinas coast. Climatology is the study of climate, and it includes historical climate characteristics, ranges of natural variations in climate, and long-term climate change. Climate also includes the ways the ocean interacts with the land and the air. This means that coastal climate studies consider both atmospheric and marine data, like maritime winds, salinity, currents, wave characteristics, and tides.

how does climate affect the carolinas coast?
The Carolinas coast has seen its fair share of hurricanes and strong coastal storms. The average return period for a hurricane is ~8-9 years for the South Carolina coast and ~5-7 years for the North Carolina coast. Both precipitation extremes of heavy rainfall and drought affect North and South Carolina coasts. Most recently, Hurricane Joaquin brought record rainfalls to South Carolina and into southeastern North Carolina. The coastal Carolinas also experience drought. Major events in 1998-2002, 2007-2008, and 2011-2012 contributed to increased salinity and saltwater intrusion in coastal water bodies.

Climate events in the Carolinas have several impacts on the coast. These include:
- Flooding
- Erosion
- Degraded water quality
- Habitat disturbance
- Degraded air quality

Many important sectors of our economy rely on coastal resources and are affected by climate:
- Water resources (e.g. availability of freshwater during drought)
- Utilities and infrastructure (e.g. increased energy demands during warmer periods, flooded roads during heavy rainfall events)
- Fisheries (e.g. changes in ocean temperature and salinity can affect fish migration and reproduction)
- Recreation and tourism (e.g. warm temperatures on the Carolinas coast are a draw for beachgoers, while storms and hurricanes can keep tourists away)

what do we know about climate change and the carolinas coast?

Sea level rise: Observations since the 1920s and 1930s indicate that the sea level in Wilmington, NC, rose at an average rate of about 0.68 feet per century; in Charleston, SC, the rate was closer to one foot per century. Globally, climate scientists expect sea level rise to range from 8 inches to 6 feet in the next 100 years; regional sea level rise may be more or less depending on regional factors such as wind patterns and vertical land movement.

More frequent rainfall extremes: Rainfall is difficult to predict over long periods of time. Climate models cannot say precisely how much average rainfall the Carolinas will get in the coming decades; however, more frequent extremes of both drought and heavy rainfall are anticipated.

Hurricane intensity: Scientists are uncertain about the frequency and tracks of hurricanes in the future. However, storms that do form will likely be stronger in terms of wind speed and rainfall amounts.

Extreme heat: While the location of coastal lands next to the ocean ameliorates some of the more extreme temperature highs experienced in upstate NC and SC, the coastal Carolinas are still subject to summer heat. Temperatures will continue to increase across the SE. Scientists project summer temperatures to increase significantly, leading to more frequent heat waves.
COMMUNITY PLANNING & ADAPTATION

City of Folly Beach, SC, Plans for Sea Level Rise in 2015 Comprehensive Plan

The City of Folly Beach is a small barrier island community that faces a variety of coastal hazards, including the threat of rising seas from both the ocean and marsh sides of the island. With technical assistance from CISA and SC Sea Grant, the city is now actively planning for long-term impacts from sea level rise and chronic erosion.

A Community-Wide Health Risk Assessment of Vulnerable Water Infrastructure in Coastal Cities

This project, funded by NOAA’s Coastal and Climate Applications (COCA) program, seeks to expand the capacity of decision makers, including public health officials, environmental agencies, emergency managers, and water/wastewater utility operators, around the issues of critical coastal water infrastructure and public health. Pilot communities include Morehead City, NC, and Charleston, SC.

South Atlantic Regional Research on Coastal Community Resilience

CISA is collaborating with researchers, Sea Grant staff, and community partners from Florida, Georgia, North Carolina, and South Carolina to conduct and evaluate a participatory process to help local governments build capacity to better visualize, understand, and plan for local coastal hazard risks. The team will use the FEMA HAZUS model coupled with improved digital elevation files to refine risk assessments. The team will use the Vulnerability, Consequences, and Adaptation Planning Scenarios (VCAPS) process to engage with the partner communities. They will also evaluate the effectiveness of VCAPS in supporting different stages of the resilience planning process.

Fostering a Citizen-Driven Sea Level Rise Task Force in the South Carolina Low Country

Stakeholders in the city of Beaufort and town of Port Royal, SC, have formed a task force to address the area’s vulnerability to sea level rise and develop adaptation strategies to address potential impacts. The task force has thirteen members, including the mayor of Beaufort and planning administrator for Port Royal.

FOSTERING NETWORKS FOR RESILIENCE

Building Regional Resilience Capacity in Charleston, SC

Established in 2015, the Charleston Resilience Network (CRN) is composed of public and private sector stakeholder organizations throughout the Charleston, SC metropolitan area that have a collective interest in the resilience of communities, critical infrastructure, and socio-economic continuity to episodic natural disasters and chronic coastal hazards. The CRN works to foster a unified strategy and provide a forum to share science-based information, educate stakeholders, and enhance long-term planning decisions that result in resilience. Learn more at www.charlestonresilience.net.

The Southeast and Caribbean Climate Community of Practice

Initiated by NOAA’s Southeast and Caribbean Regional Team (SECART) and regional Sea Grant programs, the Southeast and Caribbean Climate Community of Practice (CCoP) was created in 2010 in response to the growing need for climate extension professionals to bridge the gap between science and decision makers. Comprised of individuals from government, academic, nonprofit, and private sectors, the CCoP provides a forum for sharing lessons learned and best practices related to climate communication and adaptation. CISA is providing leadership to maintain and enhance the CCoP, which provides education and networking opportunities to increase its members’ knowledge and awareness of climate science and, ultimately, to increase adaptive capacity in the region.
