The recently developed Climate Voyager product is a web-based platform for visualizing future climate projections using a three-map layout. This interface shows the spread of future projections on a regional scale, and, by selecting a location, local projections can be viewed on the map and a time series graph that includes a historical perspective for the likely future changes.

This interactive presentation will explore how stakeholders can access, understand, and interpret these future climate projections, connecting the data with local climate-based risks and opportunities for decision making. We will use scenarios from the audience to help show how to access and interpret climate projections.
